Implementations

- HashMap

- Untyped vs Typed syntax
- ✤ For-each loop

What are Collections?

- Collections are Java objects used to store, retrieve, and manipulate other Java objects
 - Any Java object may be part of a collection, so collection can contain other collections
- Collections do not store primitives
- \oplus Java collection architecture includes:
 - Interfaces abstract data types representing collections
 - Implementation concrete implementation of collection interfaces
 - Algorithms methods for manipulating collection objects

Collection Architecture

Collection framework benefits include:

- ⊕ Uniformity
- ⊕ Faster development
- \oplus Interoperability
- \oplus Less programming

Interfaces

- Collection "uses" Iterator
- Map "uses" Collection
- Set extends Collection (subtyping)
- List extends Collection (subtyping)

Interfaces

 - ✤ For-each loop

Collection Interface

- $\ensuremath{\oplus}$ These collection objects are known as collection elements
- \oplus There is no direct implementation of this interface in JDK
 - Concrete implementations are provided for subtypes
- Collections in general can allow duplicate elements, and can be ordered
 - Unordered collections that allow duplicate elements should implement directly Collection interface

Adding Elements

 In general two methods are defined for adding elements to the collection:

```
interface Collection
{
  //...
  /**
   * Adds element to the receiver.
   * Returns true if operation is successful, otherwise return s false.
   */
 boolean add(Object element);
  /**
   * Adds each element from collection c to the receiver.
   * Returns true if operation is successful, otherwise returns false.
   */
 boolean addAll(Collection c);
```

Removing Elements

 Similarly to adding protocol, there are two methods are defined for removing elements from the collection:

```
interface Collection
{
    //...
    /**
    * Removes element from the receiver.
    * Returns true if operation is successful, otherwise returns false.
    */
    boolean remove(Object element);
    /**
    * Removes each element contained in collection c from the receiver.
    * Returns true if operation is successful, otherwise returns false.
    */
    boolean removeAll(Collection c);
}
```

Other Collection Methods

 \oplus Includes methods for:

- $\ensuremath{\oplus}$ Checking how many elements are in the collection
- $\ensuremath{\oplus}$ Checking if an element is in the collection
- ✤ Iterating through collection

```
boolean contains(Object element);
boolean containsAll(Collection c);
int size();
boolean isEmpty();
void clear();
boolean retainAll(Collection c);
Iterator iterator;
```

Iterator Interface

```
public interface Iterator
  /**
   * Returns whether or not the underlying collection has next
   * element for iterating.
   */
 boolean hasNext();
  /**
   * Returns next element from the underlying collection.
   */
  Object next();
  /**
   * Removes from the underlying collection the last element returned by next.
   */
  void remove();
```

Set Interface

♦ Set is a collection that does not contain duplicate elements

- This is supported by additional behavior in constructors and add(), hashCode(), and equals() methods
- All constructors in a set must create a set that does not contain duplicate elements
- \oplus It is not permitted for a set to contain itself as an element
- If set element changes, and that affects equals comparisons, the behavior of a set is not specified

List Interface

- \oplus Also known as sequence
- - Positional Access
 - ♦ Search

Map Interface

 \oplus Map is an object that maps keys to values

- ✤ Keys must be unique, i.e. map cannot contain duplicate keys
- Each key in the map can map to most one value, i.e. one key cannot have multiple values
- Map interface defines protocols for manipulating keys and values

Collections Architecture

- Architecture

✤ Interfaces

- ⊕ List

- + Iterator
- Implementations

 - HashMap
 - HashSet
- - Untyped vs Typed syntax
 - ✤ For-each loop

Most Commonly Used Collections

- HashMap

ArrayList

- Represents resizable-array implementation of the List interface
 - Permits all elements including null
- It is generally the best performing List interface implementation
- $\ensuremath{\oplus}$ Instances of this class have a capacity
 - It is size of the array used to store the elements in the list, and it's always at least as large as the list size
 - ✤ It grows as elements are added to the list

ArrayList Examples

HashMap

- Collection that contains pair of objects
 - ✤ Values are stored at keys
- ✤ It is a hash table based implementation of the Map interface
 - $\ensuremath{\oplus}$ Permits null values and null keys
 - The order of the map is not guaranteed
- ✤ Two parameters affect performance of a hash map:
 - $\ensuremath{\oplus}$ Initial capacity, indicates capacity at the map creation time
 - Load factor, indicates how full the map should be before increasing its size
 - \oplus 0.75 is the default

HashMap Example

HashSet

Concrete implementation of the Set interface

- Backed up by an instance of HashMap
- Order is not guaranteed
- Performance of the set is affected by size of the set and capacity of the map
 - It is important not to set the initial capacity too high, or the load factor too low if performance of iteration is important
- Elements in the set cannot be duplicated

HashSet Example

Implementations

- Java 5 Generic Collections
 Untyped vs Typed syntax
 - ♦ For-each loop

Java 5 Generic Collection

Collections use polymorphism to store objects of any type.
A drawback is type loss on retrieval.

- HashMap stores
 key/value pairs
 as java Objects.
- get() method returns a matching Object for the given key.

```
HashMap numberDictionary = new HashMap();
numberDictionary.put("1", "One");
numberDictionary.put("2", "Two");
```

```
Object value = numberDictionary.get("1");
String strValue = (String) value;
```

- The key/values in this code are actually Strings
- The return value must be type cast back to a String in order to accurately recover the stored object.

Untyped = Unsafe

- Type casting is undesirable (due to possibility of run time errors).
- Therefore, use of untyped (pre-Java 5) collections is considered 'unsafe'.
- \oplus Typed collections avoid type loss.
- ✤ Runtime checks are simplified because the type is known.

Revised syntax

 \oplus ... and on creation:

```
notes =
```

```
new ArrayList<String>();
```

 \oplus Collection types are parameterized.

Using a typed collection

```
ArrayList<String> list = new ArrayList<String>();
list.add("First element");
list.add("Second element");
String first = list.get(0);
String second = list.get(1);
```

Using a Typed Iteration

```
ArrayList list = new ArrayList();
Iterator iterator = list.iterator();
while (iterator.hasNext()
{
    String element = (String)iterator.next();
    System.out.println(element);
}
```

```
ArrayList<String> list = new ArrayList<String>();
Iterator<String> iterator = list.iterator();
while (iterator.hasNext())
{
   String element = iterator.next();
   System.out.println(element);
}

typed / safe
```

HashMaps operate with (key,value) pairs.
A typed HashMap required two type parameters:

```
private HashMap<String, String> responses;
```

• • •

```
responses = new HashMap<String, String> ();
```

HashMaps

For-each Loop

 \oplus Iteration over collections is a common operation.

 If a collections provides an Iterator, Enhanced for loop simplifies code

```
ArrayList<String> list = new ArrayList<String>();
//...
Iterator <String> iterator = list.iterator();
while (iterator.hasNext())
{
    String element = iterator.next();
    System.out.println(element);
}
```

```
ArrayList<String> list = new ArrayList<String>();
//...
for (String element : list)
{
   System.out.println(element);
}
For-each loop
```
